(54) Title: METHOD AND SYSTEM FOR PROVIDING A THIN FILM WITH A CONTROLLED CRYSTAL ORIENTATION USING PULSED LASER INDUCED MELTING AND NUCLEATION-INITIATED CRYSTALLIZATION

(57) Abstract: Method and system for generating a metal thin film with a uniform crystalline orientation and a controlled crystalline microstructure are provided. For example, a metal layer is irradiated with a pulsed laser to completely melt the film throughout its entire thickness. The metal layer can then resolidify to form grains with a substantially uniform orientation. The resolidified metal layer can be irradiated with a sequential lateral solidification technique to modify the crystalline microstructure (e.g., create larger grains, single-crystal regions, grain boundary controlled microstructures, etc.) The metal layer can be irradiated by patterning a beam using a mask which includes a first region capable of attenuating the pulsed laser and a second region allowing complete irradiation of sections of the thin film being impinged by the masked laser beam. An inverse dot-patterned mask can be used, the microstructure that may have substantially the same as the geometric pattern as that of the dots of the mask.

Method and System for Providing a Thin Film with a Controlled Crystal Orientation
Using Pulsed Laser Induced Melting and Nucleation-Initiated Crystallization

Cross-Reference to Related Application(s)

5 This application claims priority from United States Application Serial No. 60/369,186 filed April 1, 2002, the entire disclosure of which is incorporated herein by reference.

Notice of Government Rights

10 The U.S. Government may have certain rights in this invention pursuant to the terms of the Defense Advanced Research Project Agency award number N66001-98-1-8913.

Field of the Invention

15 The present invention relates to a system and process for producing a metal thin film having a uniform crystal orientation and controlled microstructure. In particular, the system and process of the present invention utilize a pulsed laser beam in conjunction with sequential lateral solidification ("SLS") techniques to produce, e.g., an aluminum thin film with, preferably, a (111) crystal orientation.

Background of the Invention

An inherent problem in the production of metallic thin films is minimizing the electro-migration that occurs in the metal interconnects. The electro-migration results in the transport of metal material of an interconnect line, and is caused when free electrons dislodge the atoms of the conductive material upon the current density increase that occurs due to smaller cross-sectional dimensions of the interconnect lines. The electro-migration occurs due to the transfer of momentum from the electrons flowing in a metal conductor when the conductor fails, because of a void or break in the conductor. This phenomenon is generally known as an "electron wind." The failure occurs most often along the grains of the conductive material since the atoms are not as firmly bound along the grains, and the grains provide efficient paths for the electron transport. These grains may extend in a direction which is parallel to the direction of the interconnect lines, i.e., along the direction of the current flow, which is considered to be particularly undesirable (i.e., such grain direction results in

an increased electro-migration). If vacancies or voids are formed in the conductive material, the void that is formed reduces the cross-sectional area in a region of the interconnect through which the current may flow, effectively raising the current density of that region of the interconnect even further. Therefore, the void may

5 become so large that an open circuit or a break in the interconnect line results.

Alternatively, the atoms of the conducting material that are dislodged may accumulate in a region of the interconnect so as to form a protrusion. If the protrusion becomes large enough, a contact with an adjacent interconnect may occur, thereby causing an undesired connection between the adjacent interconnect lines.

10 As the features of integrated semiconductor circuit chips are reduced, the cross-section of the metal interconnect lines on the integrated circuit chips are also reduced. This decrease in the cross-sectional dimensions increases the current density in the interconnect lines, which creates increased electro-migration in the metal interconnects. Moreover, the electro-migration would likely increase with a presence
15 of a random orientation of the microstructure of the thin film. Since increasing the grain size to be larger than the metallization line width and preparing semiconductor films with a uniform orientation would reduce the propensity for electro-migration failure, there is a need for a system and method to control crystallization, and produce thin films with the substantially uniform orientation of the microstructure of the thin
20 film.

Control over the thin film microstructure may be obtained through the use of sequential lateral solidification ("SLS") techniques. For example, U.S. Patent No. 6,322,625 (the "625 application"), U.S. Patent Application Serial Nos. 60/239,194 (the "194 application"), 09/390,535 (the "535 application"), 09/390,537 (the "537 application"), 60/253,256 (the "256 application"), 09/526,585 (the "585 application") and International Patent Application Nos. PCT/US01/31391 and PCT/US01/12799, the entire disclosures of which are hereby incorporated herein by reference, describe advantageous apparatus and methods for growing large grained polycrystalline or single crystal structures using energy-controllable laser pulses and small-scale
25 translation of a sample to implement the SLS techniques. As described in these patent documents, at least portions of the semiconductor film on a substrate are irradiated with a suitable radiation pulse to completely or partially melt such portions of the film throughout their thickness. In this manner, when the molten semiconductor material solidifies, a crystalline structure grows into the solidifying portions from selected
30

areas of the semiconductor film which did not undergo a complete melting.

Thereafter, the beam pulses irradiate slightly offset from the crystallized areas so that the grain structure extends into the molten areas from the crystallized areas. With the SLS techniques, and the systems described therein, crystallization may be controlled

5 to modify the microstructure of the thin film (e.g., by creating larger grains, single-crystal regions, grain-boundary-location-controlled microstructures), and produce grains with a particular orientation.

Summary of the Invention

One of the objects of the present invention is to produce at least one section of
10 a metal layer having a uniform crystal orientation and a controlled microstructure. In particular, the present invention may be used to produce an aluminum metal layer having a controlled crystal orientation of microstructures provided therein. For example, a pulsed laser beam may be utilized in conjunction with a sequential lateral solidification ("SLS") technique to produce a (111) crystal orientation of an aluminum
15 thin film with.

In one exemplary embodiment of the present invention, a method and system are provided for processing a sample having a metal layer to generate a polycrystalline film with a controlled crystal orientation. In particular, at least one portion of the metal layer can be irradiated with a pulsed laser, so that the metal layer is completely melted throughout its entire thickness. Such portion of the metal layer is then resolidified via the crystalline growth, so that the grains of the metal layer have a substantially uniform orientation therein. In another embodiment of the present invention, the metal layer may be deposited on a substrate, which may be done by sputtering, evaporation or any conventional method. In yet another exemplary
20 embodiment, the metal layer may be composed of aluminum or an aluminum alloy (e.g., an aluminum-copper alloy, an aluminum-silicon alloy, an aluminum-copper-silicon alloy etc.) In a further embodiment of the present invention the substantially uniform orientation may be a (111) orientation

In still another exemplary embodiment of the present invention, the metal
30 layer can be irradiated without patterning (i.e., flood irradiate) to obtain grains with a uniform orientation. The metal layer is then irradiated using the SLS technique, as described in the above-identified patent applications. Certain masks and mask patterns can be used for the SLS techniques to generate various shapes of grain

boundaries for modifying the microstructure. This is done by, e.g., creating larger grains, single-crystal regions, grain-boundary-location-controlled microstructures, etc.

In a still further embodiment of the present invention, a mask used during the sequential solidification technique includes a first region capable of attenuating the pulsed laser and a second region which allows substantially the entire intensity of the corresponding portion of the pulsed laser to pass therethrough. The mask may be an inverse dot-patterned mask. The entire thin film can be completely melted throughout its entire thickness and the attenuation may be such that the region of the metal layer corresponding to the first region reaches a lower temperature than the melting temperature of the metal layer and lower than that the temperature of the section of the metal layer irradiated by the beam that is shaped by the second region. In yet another embodiment of the present invention, the dot patterns of the mask can be spaced closer than the super lateral growth distance which is based on the relevant process temperature. The inverse dot-patterned mask can include dots arranged in a geometric pattern such that the microstructure of the metal layer irradiated using such mask crystallizes in substantially the same geometric pattern as the arrangement of the dots of the inverse dot-patterned mask. The dots of the inverse dot-patterned mask may also be arranged to irradiate the metal layer microstructure in a manner to a hexagonal pattern or a square pattern therein.

20 Brief Description of the Drawings

For a better understanding of the present invention, together with other and further objects thereof, reference is made to the following description, taken in conjunction with the accompanying drawings, and its scope will be pointed out in the appending claims.

Throughout the Figures, the same reference numerals and characters, unless otherwise stated, are used to denote like features, elements, components or portions of the illustrated embodiments. Moreover, while the present invention will now be described in detail with reference to the Figures, it is done so in connection with the illustrative embodiments.

25 Detailed Description

In one exemplary embodiment of the present invention, a uniform crystalline orientation of at least one section of a metal thin film may be obtained using the sequential lateral solidification process. Therefore, in order to fully understand the present invention, the sequential lateral solidification process is further described. As disclosed in aforementioned patent applications, the sequential lateral solidification ("SLS") process is a technique for producing large grained thin films through small-scale unidirectional translation of a sample between sequential pulses emitted by an excimer laser. As each pulse is absorbed by the sample, a small area of the sample is

caused to melt completely, and then resolidify laterally into a crystal region produced by the preceding pulses of a pulse set. It should be understood that various systems according to the present invention may be utilized to generate, nucleate, solidify and crystallize one or more areas on the thin film (e.g., composed of aluminum) which 5 have uniform material therein, such that at least an active region of a thin-film transistor ("TFT") may be placed in such areas. The exemplary embodiments of the systems and processes of the present invention to generate such areas, as well as those of the resulting crystallized metal thin films, shall be described in further detail below. However, it should be understood that the present invention is in no way limited to the 10 exemplary embodiments of the systems, processes and semiconductor thin films described herein.

Figure 1 shows a system that includes excimer laser 110, energy density modulator 120 to rapidly change the energy density of laser beam 111, beam attenuator and shutter 130, optics 140, 141, 142 and 143, beam homogenizer 144, lens 15 system 145, 146, 148, a mask or masking system 150, lens system 161, 162, 163, incident laser pulse 164, thin metal film sample 170, sample translation stage 180, granite block 190, support system 191, 192, 193, 194, 195, 196, and managing computer 100. As described in further detail in the '535 application, a non-processed thin film sample 170 may be processed into a single or polycrystalline metal thin film 20 by generating a plurality of excimer laser pulses of a predetermined fluence, controllably modulating the fluence of the excimer laser pulses, homogenizing the modulated laser pulses in a predetermined plane, masking portions of the homogenized modulated laser pulses into patterned beamlets, irradiating an amorphous silicon thin film sample with the patterned beamlets to effect melting of 25 portions thereof corresponding to the beamlets, and controllably translating the sample with respect to the patterned beamlets and with respect to the controlled modulation to thereby process the amorphous thin film sample into a single or polycrystalline thin film by sequential translation of the sample relative to the patterned beamlets and irradiation of the sample by patterned beamlets of varying 30 fluence at corresponding sequential locations thereon. The laser system may include a laser source, optics, mask, and projection system, which may be substantially the same as or similar to the equipment used for other SLS systems and processes.

In an exemplary embodiment of the present invention, the method and system may be used to generate metal thin films (e.g., aluminum film) with a uniform

crystalline orientation. The thin film may be composed of aluminum alloys such as, e.g., Al-Cu, Al-Si, Al-Cu-Si, etc. In such exemplary embodiment, the concentration of the impurities may preferably be less than 20%.

The aluminum thin film sample may be deposited on a substrate by various methods, such as sputtering, evaporation, etc. In one exemplary embodiment of the present invention, it is possible to use the polycrystalline aluminum films without the need to place it on a substrate. In one exemplary embodiment, at least one portion of the aluminum thin film layer is irradiated with a pulsed laser (e.g., an excimer laser) without patterning of the beam pulse (i.e. flood irradiation). The entire portion of the metal layer is completely melted, preferably throughout its entire thickness. The completely melted liquefied section of the aluminum thin film solidifies via nucleation and crystalline growth thus resulting in an aluminum thin film as shown in Figure 2. Figure 3 shows a representation of an enlarged portion of the resolidified section illustrated in Figure 2 indicating that the complete melting and solidification of the section(s) of the aluminum thin film results in grain boundaries 200 and grain shapes 202 that are relatively random.

According to another exemplary embodiment of the present invention, the resolidified (and possibly nucleated) grains of the aluminum layer provided as a substrate can have a substantially uniform orientation after irradiation and solidification. The nucleated aluminum grains likely have a uniform (111) orientation. Such exemplary orientation of the aluminum grains may preferably occur through the heterogeneous nucleation at an interface between liquid aluminum and the substrate. For example, the (111) planes of the aluminum grains likely have the lowest surface energy, which reduces the activation energy for the heterogeneous nucleation. Thus, the (111) orientation of the aluminum grains is thermodynamically preferred according to the present invention. Figure 4 shows inverse pole symbols representing an exemplary portion of the resolidified section of the aluminum thin film of Figure 2 illustrating that the crystallized aluminum grains have various orientations, and in particular, a (111) orientation. In an exemplary embodiment of the system and process according to the present invention, it is possible to obtain the (111)-oriented polycrystalline aluminum films by positioning the sample 170 in a predetermined manner and subjecting the thin film to the SLS processing. This can be done after the thin film is subject to flood irradiation.

In another exemplary embodiment of the present invention, it is possible to initially irradiate a portion of the aluminum thin film sample without patterning (i.e., by flood irradiating), so as to allow the irradiated portions of thin film to solidify, so as to obtain grains having a (111) orientation, and then irradiate such previously-
5 irradiated portion of the metal layer using the SLS process, as described in the above-identified patent applications and patents. Depending on the masks and their mask patterns (the examples of which are described and shown in the above-identified applications and patents), it is possible to generate various shapes of grain boundaries so as to modify the metal microstructure and the orientation of the grains thereof (e.g.,
10 by creating larger grains, single-crystal regions, grain-boundary-location-controlled microstructures, etc.).

The mask 150 may include a first region capable of attenuating the pulsed laser and a second region that allows the associated portions of complete pulsed laser to irradiate therethrough. For example, an inverse dot-patterned mask may be used in
15 which the dots are arranged in a geometric pattern such that the microstructure of the metal layer crystallizes substantially corresponds to the geometric shape of the arrangement of the dots of the mask pattern. In a further embodiment of the present invention, similarly to the conventional SLS techniques which utilize dot-patterned masks, the dot patterns on such mask should be spaced closer to one another than the
20 super lateral growth distance corresponding to the relevant process temperature. As described in the applications and patents identified herein above, the dot regions of the inverse dot patterned mask may be arranged to form a metal layer with a hexagonal microstructure as shown in Figure 5. In particular, the exemplary mask of Figure 5 includes a first region 500 that attenuates the beam intensity and a second
25 region 502 that allows the beam to pass therethrough to reach and irradiate the aluminum thin film. It is preferable for the energy density of the beam to be large enough to completely melt the intended sections of the aluminum thin film, including the regions masked by the dots 500. Since the dots 500 are opaque, and the beam is significantly attenuated in those regions, the aluminum thin film area positioned to be
30 irradiated by the dot regions (although completely melted) would likely not reach as high of a temperature as that of the areas outside the dot regions (which are also completely melted) as is shown in Figure 6. In particular, the temperature 501 in the attenuated region of the aluminum thin film should be lower than the melting temperature of the film so that at least some of (111) nucleated grains that are formed

remain as solids (e.g., via a previous irradiation such as the flood irradiation) to seed the molten metal around those solid regions into the (111) oriented grains.

As the film cools, the section of the aluminum thin film irradiated by the section of the laser beam masked the dot regions nucleates, thus, providing the (111) oriented seeds that grow laterally into the non-masked areas in accordance with the principles of SLS techniques described in the above-identified U.S. and International patent applications and patents. In particular the dot-patterned SLS techniques described therein. As described in these patent documents, the microstructure that is obtained depends on the geometry of the dot regions of the mask 150. Therefore, as shown in Figures 7 and 8, the use of the exemplary inverse dot-patterned mask of Figure 5 to mask the laser beam and irradiate the aluminum thin film results in crystallized aluminum film with a hexagonal microstructure. Figure 8 shows an enlarged representation of a portion of the section provided in Figure 7 further illustrating the locations and shapes of the grain boundaries 800, 802, respectively. Figure 9 shows inverse pole symbols representing the portion of the section provided in Figure 8 that illustrate that the crystallized aluminum grains have substantially a (111) orientation. In a further exemplary embodiment of the present invention, the dot regions of the inverse dot patterned mask may be arranged so as to generate the sections of the metal thin film with square microstructure therein.

Referring to Figure 10, exemplary steps executed by computer 100 of Figure 1 to control the irradiation and grain orientation of the metal thin film is described. The various electronics of the system shown in Figure 1 are initialized by the computer to initiate the process in step 1000. A thin metal (aluminum) film sample 170 is then loaded onto the sample translation stage in step 1005. It should be noted that such loading may be either manual or robotically implemented under the control of the computer 100.

Next, the sample translation stage 180 is moved into an initial position in step 1010, which may include an alignment with respect to reference features on the sample 170. The various optical components of the system are focused in step 1015 if necessary. The laser is then stabilized in step 1020 to a desired energy level and repetition rate, as needed to fully melt the metal thin film sample 170 in accordance with the particular processing to be carried out. If necessary, the attenuation of the laser pulses is finely adjusted (step 1025).

Next, the sample 170 is positioned to point the beam to impinge on the first section of sample in step 1030. The beam 149 is masked with the appropriate mask pattern of the mask 150 (step 1035). It is also possible to not mask the beam prior to its impingement of the sample 170. After the beam 149 is masked to become a
5 masked beam pulse 164, the masked beam pulse 164 irradiates at least one section of the metal (aluminum) thin film sample 170 to produce grains that have a particular (e.g., - 111) orientation in step 1040. Then, in step 1045, it is determined whether all intended areas of the thin metal film sample 170 have been irradiated in a predetermined manner. If not, the sample 170 is then translated in the X and/or Y
10 directions in step 1050 for a distance which is less than the super lateral grown distance of the metal thin film using the SLS and/or non-SLS techniques. After processing all of the desired sections of the metal thin film sample 170, the beam and hardware are shut off in step 1055 and the process is completed in step 1060. If processing of additional samples is desired or steps 1005 – 1050 may be repeated for
15 each such sample.

In addition, it is also possible to obtain the (111) oriented grains using the SLS techniques described above and without the flood irradiations being effectuated on the aluminum thin film prior to such SLS processing. In particulars, the desired sections of the aluminum thin film 170 are irradiated using the one of the patterned masks
20 described above (e.g., the dot-patterned mask, the hexagonal-shaped mask, the rectangular shaped mask, etc.) and the SLS techniques in order to nucleate center areas corresponding to the such shapes (which allow some or all of the irradiation of the beam pulse to pass therethrough). The resolidified desired regions of the aluminum thin film 170 result in the (111) oriented grains, which are also grain
25 boundary controlled grains. Accordingly, it is not necessary to subject the aluminum thin film 170 to flood irradiation prior to it being irradiated using the SLS processing technique.

The foregoing merely illustrates the principles of the invention. Various modifications and alterations to the described embodiments will be apparent to those
30 skilled in the art in view of the teachings herein. For example, while the above embodiment has been described with respect to at least partial lateral solidification and crystallization of the semiconductor thin film, it may apply to other materials processing techniques, such as micro-machining, photo-ablation, and micro-patterning techniques, including those described in the above-identified patent documents. The

various mask patterns and intensity beam patterns described in the above-referenced patent application may also be utilized with the process and system of the present invention. It will thus be appreciated that those skilled in the art will be able to devise numerous systems and methods which, although not explicitly shown or described 5 herein, embody the principles of the invention and are thus within the spirit and scope of the present invention.

Claims

1. A method for processing a sample having a metal thin film provided thereon to generate a polycrystalline film with a substantially uniform orientation, comprising the steps of:
 - 5 (a) irradiating at least one portion of the metal thin film with a pulsed laser to completely melt the at least one portion throughout its entire thickness; and
 - (b) allowing the melted metal thin film to re-solidify after the at least one portion is melted, wherein the grains of the at least one resolidified portion of the metal thin film have the substantially uniform orientation.
- 10 2. The method according to claim 1, wherein the metal thin film is deposited on a substrate.
- 15 3. The method according to claim 2, wherein the metal thin film is deposited on a substrate by at least one of a sputtering procedure, an evaporation procedure and a further thin film deposition procedure.
4. The method according to claim 1, wherein the metal thin film is composed of aluminum.
- 20 5. The method according to claim 1, wherein the metal thin film is composed of an aluminum alloy, the aluminum alloy including at least one of an aluminum-copper alloy, an aluminum-silicon alloy and an aluminum-copper-silicon alloy.
6. The method according to claim 1, wherein the substantially uniform orientation is a (111) orientation.
7. The method according to claim 1, further comprising the step of:
 - 25 (c) irradiating the at least one portion of the metal thin film with the laser pulse based on a sequential lateral solidification technique.
8. The method according to claim 7, wherein the laser pulse irradiating the at least one portion is patterned using a mask to modify a shape of the laser pulse.

9. The method according to claim 8, wherein the mask is comprised of a first region capable of attenuating the pulsed laser and a second region allowing a significant section of the laser beam impacting the second region to pass therethrough.
- 5 10. The method according to claim 9, wherein the mask is an inverse dot-patterned mask, and wherein the second region includes opaque array patterns which include at least one of dot-shaped areas, hexagonal-shaped areas and rectangular-shaped areas.
- 10 11. The method according to claim 10, wherein each portion of the metal thin film is completely melted throughout its entire thickness, and wherein an attenuation of the laser beam produced by the first region impinges associated section of the thin film to reach a temperature that is lower than a melting temperature of the metal thin film and lower than a temperature as further sections of the thin film corresponding with the areas irradiated by the second region.
- 15 12. The method according to claim 11, wherein dot patterns of the mask are spaced closer than a super lateral growth distance corresponding to a resolidification process temperature of the metal thin film.
13. The method according to claim 10, wherein the inverse dot-patterned mask is comprised of dots has a geometric pattern such that upon the irradiation of the metal thin film, a microstructure of the metal thin film solidifies and crystallizes in substantially the same geometric pattern as the pattern of the inverse dot-patterned mask.
- 20 25 14. The method according to claim 13, wherein the dots of the inverse dot-patterned mask are arranged in a pattern such that upon the irradiation of the metal thin film with the masked laser beam, a microstructure of the metal thin film is formed having one of a hexagonal pattern, a rectangular pattern and a square pattern.

15. The method according to claim 7, wherein, in step (a), a width of the at least one irradiated portion is greater than a super-lateral growth width of the metal thin film.
16. The method according to claim 1, wherein step (a) is performed using a sequential lateral solidification technique, and wherein, upon the execution of step (a), in step (b), grain-boundary location controlled grains are formed in the at least one portion of the metal thin film.
5
17. A system for producing at least one section of a polycrystalline metal film with a substantially uniform orientation, comprising:
10
 - a logic arrangement which is operable to:
 - (a) irradiate at least one portion of the at least one portion of the metal thin film to completely melt the at least one portion of the metal thin film throughout its entire thickness, and
 - (b) allow the at least one portion of the melted metal thin film to re-solidify after the at least one is melted, wherein the grains of the at least one portion have the substantially uniform orientation upon the re-solidification.
18. The system according to claim 17, wherein the metal thin film is deposited on a substrate.
15
20. 19. The system according to claim 18, wherein the metal thin film is deposited on a substrate by at least one of a sputtering procedure, an evaporation procedure and a further thin film deposition procedure.
20. The system according to claim 17, wherein the metal thin film is composed of aluminum.
25
21. The system according to claim 17, wherein the metal thin film is composed of an aluminum alloy, the aluminum alloy including at least one of an aluminum-copper alloy, an aluminum-silicon alloy and an aluminum-copper-silicon alloy.

22. The method according to claim 17, wherein the substantially uniform orientation is a (111) orientation.
23. The system according to claim 17, where the logic arrangement is further operable to irradiate the at least one portion of the thin film sample with a sequential lateral solidification technique.
5
24. The system according to claim 23, wherein the laser pulse irradiating the at least one portion is patterned using a mask to modify a shape of the laser pulse.
25. The system according to claim 24, wherein the mask is comprised of a first
10 region capable of attenuating the pulsed laser and a second region allowing a significant section of the laser beam impacting the second region to pass therethrough.
26. The system according to claim 25, wherein the mask is an inverse dot-patterned mask, and wherein the second region includes opaque array patterns
15 which include at least one of dot-shaped areas, hexagonal-shaped areas and rectangular-shaped areas.
27. The system according to claim 26, wherein each portion of the metal thin film is completely melted throughout its entire thickness, and wherein an attenuation of the laser beam produced by the first region impinges associated
20 section of the thin film to reach a temperature that is lower than a melting temperature of the metal thin film and lower than a temperature as further sections of the thin film corresponding with the areas irradiated by the second region.
28. The system according to claim 27, wherein dot patterns of the mask are spaced
25 closer than a super lateral growth distance corresponding to a resolidification process temperature of the metal thin film.
29. The system according to claim 28, wherein the inverse dot-patterned mask is comprised of dots has a geometric pattern such that upon the irradiation of the metal thin film, a microstructure of the metal thin film solidifies and

crystallizes in substantially the same geometric pattern as the pattern of the inverse dot-patterned mask.

30. The system according to claim 29, wherein the dots of the inverse dot-patterned mask are arranged in a pattern such that upon the irradiation of the metal thin film with the masked laser beam, a microstructure of the metal thin film is formed having one of a hexagonal pattern, a rectangular pattern and a square pattern.
5
31. The system according to claim 17, wherein the logic arrangement irradiates the at least one portion of metal using a sequential lateral solidification technique, and wherein, upon the completion of step (b), grain-boundary location controlled grains are formed in the at least one portion of the metal thin film.
10
32. A polycrystalline metal film, comprising:
at least one portion which is irradiated to be completely melted
15 throughout its entire thickness, wherein the at least one portion is re-solidified after being melted, and wherein the at least one portion include grains which have a substantially uniform orientation upon the re-solidification of the at least one portion.
